# The category of twisted objects $C^{(1)}$

### 1.1 Twisted objects

1.1.1

Let  $c \in \mathsf{Ob}\, \mathcal{C}$  be an object of a category  $\mathcal{C}$  and

$$\tau \in \operatorname{End}_{\mathcal{C}} c$$

be its endomorphism. We shall refer to  $(c, \tau)$  as a twisted object (in  $\mathcal{C}$ ).

#### 1.1.2 Morphisms between twisted objects

Given two twisted objects  $(c,\tau)$  and  $(c',\tau')$ , a morphism  $\alpha \in \operatorname{Hom}_{\mathbb{C}}(c,c')$  defines a morphism

$$(c,\tau) \longrightarrow (c',\tau')$$

if  $\alpha \circ \tau = \tau' \circ \alpha$ , i.e., if the following diagram commutes

$$\begin{array}{ccc}
c & \xrightarrow{\alpha} & c' \\
\tau & & \uparrow & \uparrow \\
c & \xrightarrow{\alpha} & c'
\end{array}$$

1.1.3

We shall denote the category of twisted objects in  $\,{\mathfrak C}\,$  by  $\,{\mathfrak C}^{\langle \tau\rangle}$  .

## 1.2 The category of unary structures

1.2.1 Set $^{\langle 1 \rangle}$ 

The category of *twisted sets* is the same as the category of *unary algebraic structures*. We shall denote it  $\mathbf{Set}^{\langle 1 \rangle}$ .

## 1.2.2 Example: the canonical unary structure $(X,^+)$ on a well-ordered set $(X, \leq)$

Let  $(X, \leq)$  be a well-redred set. We define the associated successor operation as follows

$$x \longmapsto x^+ := \inf\{y \in X \mid x \prec y\} \qquad (x \in X). \tag{1}$$

Exercise 1 Show that

$$x^{+} = \begin{cases} x & \text{when } x \text{ is the greatest element of } (X, \leq) \\ \min\{y \in X \mid x < y\} & \text{otherwise} \end{cases}$$
 (2)

Solution. In any ordered set  $(X, \leq)$  the infimum of the empty subset is the greatest element of  $(X, \leq)$  and the set

$$\{ y \in X \mid x \prec y \} \tag{3}$$

is empty precisely when x is a maximal element of  $(X, \leq)$ . A well-ordered set is linearly ordered, hence any two maximal elements are equal. In particular, a maximal element in a well-ordered set is the greatest element of  $(X, \leq)$ .

Any other element x' is *smaller* than the greatest element, hence

$$\{y \in X \mid x' \prec y\}$$

is not empty. In a well-ordered set every nonempty subset has the smallest element, hence

$$\inf\{\gamma \in X \mid x' \prec \gamma\} = \min\{\gamma \in X \mid x' \prec \gamma\}.$$

#### 1.2.3 Invariant subsets

We say that a subset  $A \subseteq X$  is invariant under  $\tau$  or,  $\tau$ -invariant, if  $\tau_*A \subseteq A$ , i.e., if

$$\tau(x) \in A \qquad (x \in A) \,. \tag{4}$$

#### 1.2.4 A remark about notation

Displayed expression (4) is an abreviated form of the statement:

$$\tau(x) \in A$$
 whenever  $x \in A$ .

Equivalently, the same can be stated as

for every 
$$x \in A$$
, one has  $\tau(x) \in A$ 

and, in an abbreviated form,

$$\forall_{x \in A} \ \tau(x) \in A$$
.

#### 1.2.5

A subset A of X is invariant if and only if the diagram

$$\begin{array}{ccc} A & \longleftarrow & X \\ & & \uparrow^{\tau} \\ A & \longleftarrow & X \end{array}$$

admits a completion to a commutative diagram

$$\begin{array}{ccc}
A & \longrightarrow & X \\
\uparrow & & \uparrow^{\tau} \\
A & \longrightarrow & X
\end{array}$$

#### 1.2.6 The induced operation on an invariant subset

The operation represented by the blue arrow is unique. We refer to it as the operation induced by  $\tau$  on A.

Indeed, if au' and au'' are two such operations and  $\iota$  denotes the canonical inlusion of X' into X, then

$$\iota \circ \tau' = \tau \circ \iota = \iota \circ \tau''.$$

Since  $\iota$  is *injective*, it is a monomorphism in the category of sets. Hence,  $\tau' = \tau''$ .

Generally, the induced operation on an invariant subset  $A \subseteq X$  is denoted  $\tau$ , the same way as the operation on X.

**Exercise 2** Show that, for any homomorphism  $f:(X,\tau)\longrightarrow (X',\tau')$ , one has

$$f_*(\tau_* X) \subseteq \tau_*' X' \,. \tag{5}$$

**Exercise 3** Show that  $\tau_* X$  is an invariant subset of  $(X, \tau)$ .

# 2 The category of nullary-unary structures

# 2.1 $\operatorname{Set}^{\langle o_1 \rangle}$

#### 2.1.1 Objects

We shall denote by  $Set^{(oi)}$  the category of algebraic structures consisting of a set X equipped with a single nullary operation, i.e., a distinguished element

$$a \in X$$

and a single unary operation

$$\tau \colon X \to X$$
.

#### 2.1.2 Morphisms

Homomorphisms  $f: (X, a, \tau) \longrightarrow (X', a', \tau')$ , i.e., functions  $f: X \to X'$  such that

$$f(a) = a'$$

and

$$f(\tau(x)) = \tau'(f(x)) \qquad (x \in X),$$

are declared to be morphisms.

### **2.1.3** Example: $(X, \min X, ^+)$

If  $(X, \leq)$  is a nonempty well-redered set, then  $(X, \min X, ^+)$  is nullary-unary structure. We shall refer to it as the *canonical nullary-unary* structure of a well-ordered set.

## 2.1.4 Example: $\left(\operatorname{End}_{\mathcal{C}^{(i)}}(c,\tau), \tau, \tau_{\bullet}\right)$

For any twisted object  $(c, \tau)$ , post-composition with  $\tau$ ,

$$\lambda \longmapsto \tau_{\bullet}\lambda := \tau \circ \lambda \qquad (\lambda \in \operatorname{End}_{\mathcal{O}(\iota)}c)$$

defines a unary operation  $\tau$ . on the set  $X = \operatorname{End}_{\mathcal{C}^{(t)}}(c,\tau)$  of endomorphisms of  $(c,\tau)$  while  $\tau$  is a distinguished element of  $\operatorname{End}_{\mathcal{C}^{(t)}}(c,\tau)$ .

## **2.1.5** Example: $\left(\operatorname{End}_{\mathcal{C}^{(1)}}(c,\tau),\operatorname{id}_{c},\tau_{\bullet}\right)$

If c admits an identity endomorphism, then  $\mathrm{id}_c$  is another distinguished element of  $\mathrm{End}_{\mathcal{C}^{(1)}}(c,\tau)$ .

# 2.2 An initial object of Set (OI)

**2.2.1** 
$$(N, \mathbf{0}, \sigma)$$

In this chapter  $(N, o, \sigma)$  denotes an initial object of category  $\mathbf{Set}^{(o_1)}$ .

#### 2.2.2

Since  $Set^{\langle OI \rangle}$  is a unital category, any two initial objects in  $Set^{\langle OI \rangle}$  are isomorphic and such an isomorphism is *unique*. The question of existence of initial objects in  $Set^{\langle OI \rangle}$  will be addressed later.

### 2.2.3 'o'

We shall denote the distinguished element of an initial object by 0 and will refer to the unary operation as the *successor operation*. To keep notation simple, we will often omit the parentheses around the argument of  $\sigma$  when the argument is denoted by a single symbol.

#### 2.2.4 '1', '2', etc.

It is convenient to have separate notation for  $\sigma o$  and  $\sigma(\sigma o)$ : we shall denote  $\sigma o$  by digit 1 and  $\sigma 1$  by digit 2. We can similarly denote  $\sigma o$  by digit 3, and so on.

## 2.3 Minimal algebraic structures

#### 2.3.1

We shall say that an algebraic structure  $(X, (\mu_i)_{i \in I})$  is minimal if X is the only subset of X that is closed under each operation  $\mu_i$ . If we separate nullary and nonnullary operations,

$$I = I_o \cup I_{>o}$$

where

$$\forall_{i \in I_{\circ}} \operatorname{arity}(\mu_i) = o$$
 and  $\forall_{i \in I_{\circ}} \operatorname{arity}(\mu_i) > o$ ,

then  $(X, (\mu_i)_{i \in I})$  is a minimal structure precisely when the set of distinguished elements

$$\{\mu_i \mid i \in I_o\}$$

generates the algebraic structure  $(X, (\mu_i)_{i \in I_{>0}})$ .

In particular, a minimal algebraic structure is nonempty precisely when at least one operation  $\mu_i$  is nullary.

#### 2.3.2 Initial objects in the categories of algebraic structures are minimal

The following lemma is a simple corollary of the definitions of an initial object and of a minimal algebraic structure.

Lemma 2.1 An initial object in the category of algebraic structures of any type is a minimal structure.

*Proof.* Suppose that an algebraic structure  $(X, (\mu_i)_{i \in I})$  is an initial object and let  $A \subseteq X$  be a subset closed under all operations  $\mu_i$ . Then, the canonical inclusion  $\iota : A \hookrightarrow X$  is a homomorphism. In view of  $(X, (\mu_i)_{i \in I})$  being an initial object, there exists a homomorphism  $f : X \to A$ . The composite  $\iota \circ f$  is an endomorphism of  $(X, (\mu_i)_{i \in I})$ . An initial object in a unital category has only one endomorphism, namely the identity endomorphism. It follows that

$$\iota \circ f = \mathrm{id}_X$$
.

In particular,  $\iota$  is surjective and this means that A=X.

#### 2.3.3 The Principle of Mathematical Induction

In the special case of nullary-unary structures, we obtain the following corollary.

Corollary 2.2 (The Principle of Mathematical Induction) If  $E \subseteq N$ ,  $o \in E$  and  $\sigma_*E \subseteq E$ , then E = N.

Corollary 2.3 One has

$$N = \{ \mathbf{o} \} \cup \sigma_* N \,. \tag{6}$$

In other words, if  $n \neq 0$ , then there exists  $m \in N$  such that  $\sigma m = n$ .

*Proof.* The subset  $E = \{o\} \cup \sigma_* N$  is closed under o and  $\sigma$ , hence Corollary 2.2 applies.  $\square$ 

#### 2.3.4

Consider the canonical nullary-unary structure  $(X, a, ^+)$  of the well-ordered set  $X = \{a, b\}$  where a < b.

Exercise 4. Show that the unique homomorphism

$$f:(N,o,\sigma)\longrightarrow (X,a,^+)$$

sends every  $n \neq 0$  to b.

Solution. In view of Corollary 2.3, every  $n \neq 0$  belongs to  $\sigma_*N$ . By Exercise 2

$$f_*(\sigma_* N) \subseteq ()_*^+ X = \{b\}.$$

Corollary 2.4 One has

$$o \notin \sigma_* N$$
. (7)

In particular,

$$N \ni \sigma_* N$$
. (8)

**Lemma 2.5** Let X be a set and  $f: X \longrightarrow \mathcal{P}X$  be any function Then the subset

$$A \coloneqq \{x \mid x \notin f(x)\} \tag{9}$$

is not in the image of f. In particular, f is not surjective.

Exercise 5 Prove Lemma 2.5.

**Corollary 2.6** For every set X, there exists a set Y such that  $X \neq Y$ .

*Proof.* Suppose that there exists a set X, such that every set Y is a subset of X. Then

$$\mathcal{P}X \subseteq X$$
.

If so, then the function

$$f: X \longrightarrow \mathscr{P}X, \qquad f(x) = \begin{cases} x & \text{if } x \in \mathscr{P}X \\ \emptyset & \text{otherwise} \end{cases}.$$

is surjective. That contradicts Lemma 2.5.

Corollary 2.7 For every set X, there exists a set  $X' \neq X$  such that

$$X' = X \cup \{\gamma\} .$$

*Proof.* A set Y is not equal to a set X precisely when there exists  $y \in Y$  such that  $y \notin X$ . Thus, the set  $X \cup \{y\}$  is not equal to X.

#### 2.3.5

Recall that a set X is *infinite* if there exists a left-invertible unary operation  $\tau \in \operatorname{Op}_{{}_{\mathrm{I}}} X$  that is not rright-invertible.

Exercise 6 Show that  $\tau \in \operatorname{Op}_{\scriptscriptstyle \rm I} X$  is left-invertible and not right-invertible if and only if  $\tau$  is injective and  $X \ni \tau_* X$ .

**Theorem 2.8** If  $(N, o, \sigma)$  is an initial object in the category of nullary-unary structures, then  $\sigma$  is injective and

$$N \setminus \sigma_{\star} N = \{ \mathbf{o} \} \,. \tag{10}$$

In particular, N is an infinite set.

Proof. In view of Corollary 2.7, there exists a set

$$N' = N \cup \{\gamma\}$$

such that  $y \notin N$ . Let  $f: N' \longrightarrow N$  be the function

$$f(x) = \begin{cases} \sigma x & \text{if } x \in N \\ 0 & \text{if } x = y \end{cases}$$

and  $\tau = \iota \circ f$  be the composite of f and the canonical inclusion  $\iota : N \hookrightarrow N'$ .

**Exercise** 7 Show that f is a homomorphism  $(N', y, \tau) \longrightarrow (N, o, \sigma)$ .

The composite of f with the unique homomorphism

$$g:(N,o,\sigma)\longrightarrow(N',\gamma,\tau)$$
 (11)

is an endomorphism of  $(N, o, \sigma)$  and, therefore, is the identity function,

$$f \circ g = \mathrm{id}_{N} \ . \tag{12}$$

Consider the subset of N,

$$E = \{ n \in N \mid g(\sigma n) = n \}.$$

Since g is a homomorphism (11), one has

$$g(\mathbf{1}) = g(\sigma \mathbf{0}) = \tau(g(\mathbf{0})) = \tau(y) = \mathbf{0},$$

i.e.,  $o \in E$ . If  $n \in N$ , then

$$g(\sigma\sigma n) = \tau(g(\sigma n)) = \tau(n) = \sigma n$$
,

i.e.,  $\sigma n \in E$ . By Corollary 2.2, one has E = N. It follows that

$$\pi: N \longrightarrow N, \qquad \pi(n) = \begin{cases} g(n) & \text{if } n \in \sigma_* N \\ 0 & \text{if } n = 0 \end{cases}$$
 (13)

is a left-inverse of  $\sigma$ . In view of  $o \notin \sigma_* N$ , cf. Corollary 2.4, successor operation  $\sigma$  is not surjective and, thus, is not right-invertible.

#### 2.3.6 The predecessor operation

We shall refer to the left-inverse of  $\sigma$  defined in (13) as the predecessor operation.

Note that g is, by definition, surjective. In view of Identity (12), g is injective, hence g is an isomorphism and f is its inverse.

#### 2.4 Recursively defined sequences

#### 2.4.1 'Sequences'

Any function

$$N \longrightarrow X$$
,  $n \longmapsto x_n \quad (n \in N)$ ,

from the underlying set of an initial object to a set X will be called a sequence of elements of X. Generic notation for a sequence is  $(x_n)_{n\in\mathbb{N}}$  or, in an abbreviated form,  $(x_n)$ .

#### 2.4.2 A recursive definition

We say that a sequence  $(x_n)$  is recursively defined if there are given: an element  $a \in X$ , and a sequence of unary operations  $(\tau_n)$  on X, such that

$$x_{o} = a \tag{14}$$

and

$$x_{\sigma n} = \tau_n(x_n) \qquad (n \in N) . \tag{15}$$

#### 2.4.3 Recursive data: the initial term and the recursive step sequence

Here, a is called the *initial term* of the sequence while  $(\tau_n)$  is referred to as the *recursive step sequence*. We shall refer to (14) as the *initial condition* and to (15) as the *recursive step condition*.

#### 2.4.4 Uniqueness of a recursively defined sequence

Uniqueness of a sequence defined by given recursive data is an immediate consequence of Corollary 2.2.

**Lemma 2.9** If  $(x_n)$  and  $(x'_n)$  are two sequences defined by the same recursive data, cf. (14)–(15), then they are equal.

Proof. Consider the set

$$E = \{ n \in N \mid x_n = x'_n \}.$$

The two sequences satisfy the same initial condition precisely when  $o \in E$ . For any  $n \in E$ , we have

$$x_{\sigma n} = \tau_n(x_n) = \tau_n(x'_n) = x'_{\sigma n},$$

since both sequences satisfy the same recursive step condition. It follows that E = N, cf. Corollary 2.2.

#### 2.4.5

A homomorphism

$$\mathbf{x}:(N,o,\sigma)\longrightarrow(X,a,\tau),\qquad n\longmapsto x_n,$$

in  $\mathbf{Set}^{\langle \text{or} \rangle}$  is the same as a sequence  $(x_n)$  defined by recursive data with the *constant* recursive step sequence

$$\tau_n = \tau$$
  $(n \in N)$ .

Existence as well as uniqueness of such a sequence is, therefore, equivalent to  $(N, o, \sigma)$  being an initial object of category  $\mathbf{Set}^{(oi)}$ .

#### 2.4.6

Existence of a sequence defined by any recursive step sequence will be established later.

#### 2.5 Powers of an element in a binary structure

#### 2.5.1 The left-multiplication-by-an-element operation

Let  $(B,\cdot)$  be a binary structure and  $\lambda_b$  be the operation on the underlying set B

$$x \mapsto \lambda_b(x) := bx \qquad (x \in B),$$
 (16)

that multiplies an element  $x \in B$  on the left by a given element  $b \in B$ .

#### 2.5.2 The left powers sequence

Let  $(p_n)$  be the sequence in B defined by the unique homomorphism

$$\mathbf{p}: (N, \mathbf{o}, \sigma) \longrightarrow (B, b, \lambda_b). \tag{17}$$

Note that

$$p_0 = b$$
,  $p_1 = b \cdot b$ ,  $p_2 = b(b \cdot b)$ ,  $p_3 = b(b(b \cdot b))$ , ...

#### 2.5.3 The centralizer of an element

The set of elements  $x \in B$  that commute with a given element  $a \in B$ ,

$$C_a(B,\cdot) := \{ x \in B \mid ax = xa \}, \tag{18}$$

is called the centralizer of a.

**Exercise 8** Show that the monoid of endomorphisms of a twisted set  $(X, \tau)$  coincides with the centralizer of  $\tau$ ,

$$\operatorname{End}_{\operatorname{Cor}^{(1)}}(X,\tau) = C_{\tau}\left(\operatorname{Op}_{\tau}X,\circ\right),\,$$

in the monoid of unary operations on X

$$Op_{\tau}X := End_{Set}X$$
.

Exercise 9 Suppose that binary operation  $\cdot$  is associative. Show that the centralizer of every element is closed under operation  $\cdot$ .

In other words, the centralizer of every element in a semigroup is a subsemigroup.

#### 2.5.4

In particular, in a semigroup, if a commutes with b, then the centralizer  $C_a(B,\cdot)$  is invariant under  $\lambda_b$ . It follows that there exists a homomorphism

$$(N, o, \sigma) \longrightarrow (C_a(B, \cdot), b, \lambda_b).$$
 (19)

Its composition with the inclusion homomorphism  $C \hookrightarrow B$  must coincide, in view of  $(N, o, \sigma)$  being an initial object, with homomorphism (17). It follows that

$$p_n \in C_a(B,\cdot)$$
  $(n \in N),$ 

i.e.,

$$p_n a = a p_n \qquad (n \in N)$$

and we establish the following important fact.

Lemma 2.10 In a semigroup:

- (a) if b commutes with a, then each  $p_n$  commutes with a;
- (b) powers  $p_n$  of any element commute with each other, i.e.,

$$p_m p_n = p_n p_m \qquad (m, n \in N). \tag{20}$$

Part (b) is a corollary of Part (a): b commutes with itself, hence b commutes with every  $p_n$ . This in turn, implies, by Part (a) again, that every  $p_m$  commutes with every  $p_n$ .

#### 2.5.5 The right powers sequence

Let  $(q_n)$  be the sequence in B defined by the unique homomorphism

$$\mathbf{q}:(N,\mathbf{0},\sigma)\longrightarrow(B,b,\rho_b) \tag{21}$$

where  $\rho_b$  is the operation of right multiplication by b

$$x \longmapsto \rho_b(x) := xb \qquad (x \in B). \tag{22}$$

Note that

$$q_0 = b$$
,  $q_1 = b \cdot b$ ,  $q_2 = (b \cdot b)b$ ,  $q_3 = ((b \cdot b)b)b$ , ...

Exercise 10 Show that in a semigroup the left and the right powers of an element coincide

$$p_n=q_n \qquad (n\in N).$$

Solution. Consider the set

$$E = \{ n \in N \mid p_n = q_n \}.$$

The initial terms of both sequences coincide,

$$p_{o} = b = q_{o},$$

hence  $o \in E$ . If  $n \in E$ , then

$$p_{\sigma n} = b p_n = p_n b = q_n = q_{\sigma n}$$

in view of the fact that  $p_n$  commutes with b, cf. Lemma 2.10. Thus, E is closed under 0 and  $\sigma$  and, by Corollary 2.2, E = N.

#### 2.5.6 Powers of an element in a monoid

Suppose that  $e \in B$  is an identity element in a semigroup  $(B, \cdot)$ . Define the sequence  $(b^n)$  to be the unique homomorphism

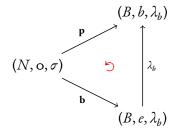

$$\mathbf{b}:(N,o,\sigma)\longrightarrow(B,e,\lambda_b)$$
.

Note that

$$b^{\circ} = e, \qquad b^{\scriptscriptstyle I} = b^{\sigma \circ} = b \cdot b^{\circ} = b \cdot e = b, \qquad b^{\scriptscriptstyle 2} = \sigma^{\sigma \scriptscriptstyle I} = b \cdot b^{\scriptscriptstyle I} = b \cdot b, \qquad \dots$$
 (23)

#### 2.5.7 A relation between the sequence of powers in a semigroup and in a monoid

Uniqueness of a homomorphism  $(N, o, \sigma) \longrightarrow (B, b, \lambda_b)$  implies that the following diagram

commutes. In other words,

$$p_n = \lambda_b(b^n) = b^{\sigma n} \qquad (n \in N). \tag{24}$$

In particular, we have the following corollary of Lemma 2.10.

#### Corollary 2.11 In a monoid:

- (a) if b commutes with a, then each  $b^n$  commutes with a;
- (b) if b commutes with a, then, for any  $m, n \in N$ ,  $b^n$  commutes with  $a^m$ ;
- (c) powers  $b^n$  of any element commute with each other, i.e.,

$$b^m b^n = b^n b^m \qquad (m, n \in N). \tag{25}$$

*Proof.* If either m or n are equal 0, then one of the factors in Equality (25) is the identity element, hence that Equality holds. If both m and n are not zero, then there exist  $k, l \in N$  such that

$$\sigma k = m$$
 and  $\sigma l = n$ ,

cf. Corollary 2.3, and therefore

$$b^m b^n = p_k p_l = p_l p_k = b^n b^m,$$

in view of Identity (24) combined with Lemma 2.10.

#### 2.5.8 Injectivity and surjectivity of the powers of a unary operation

Let  $\tau \in \mathsf{Op}_{\tau}$  be a unary operation on a set X.

Exercise 11 Show that

if 
$$\tau$$
 is injective, then  $\tau^n$  is injective for every  $n \in N$ . (26)

Exercise 12 Show that

if there exists 
$$n \neq 0$$
, such that  $\tau^n$  is injective, then  $\tau$  is injective. (27)

Exercise 13 Show that

if 
$$\tau$$
 is surjective, then  $\tau^n$  is surjective for every  $n \in N$ . (28)

Exercise 14. Show that

if there exists 
$$n \neq 0$$
, such that  $\tau^n$  is surjective, then  $\tau$  is surjective. (29)

#### 2.6 The sequence of products of elements of a semigroup

**2.6.1** 
$$(B^N, \mathbf{b}, \lambda_{\mathbf{b}} \circ \sigma^{\bullet})$$

Consider the semigroup  $(B^N, \cdot)$  of sequences of elements of a semigroup  $(B, \cdot)$  equipped with the unary operation

$$\lambda_{\mathbf{b}} \circ \sigma^{\bullet} : \mathbf{x} \longmapsto \lambda_{\mathbf{b}} (\sigma^{\bullet} \mathbf{x}) = (b_{n} x_{\sigma n}).$$
 (30)

2.6.2

Let

$$(N, o, \sigma) \longrightarrow (B^N, \mathbf{b}, \lambda_{\mathbf{b}} \circ \sigma^{\bullet}), \qquad m \longmapsto \mathbf{p}_m = (p_{mn})_{n \in N},$$
 (31)

be the unique homomorphism. It is a unique sequence-of-sequences of elements of B that satisfies the identity

$$\mathbf{p}_{\sigma m} = \mathbf{b} \sigma^{\bullet} \mathbf{p}_{m} \qquad (m \in N) . \tag{32}$$

Lemma 2.12 One has the identity

$$\mathbf{p}_{\sigma m} = \mathbf{p}_m \left(\sigma^{\sigma m}\right)^{\bullet} \mathbf{b} \qquad (m \in N)$$
(33)

Explicitly, Identity (33) has the form

$$p_{\sigma m,n} = p_{mn} b_{\sigma^{\sigma m}(n)}, \qquad (mn, \in N).$$
(34)

Proof. Consider the set

$$E = \left\{ m \in N \mid \mathbf{p}_{\sigma m} = \mathbf{p}_m \left( \sigma^{\sigma m} \right)^{\bullet} \mathbf{b} \right\}.$$

One has

$$\mathbf{p}_{\sigma \circ} = \mathbf{b} \sigma^{\bullet} \mathbf{p}_{\circ} = \mathbf{b} \sigma^{\bullet} \mathbf{b} = \mathbf{p}_{\circ} (\sigma^{{\scriptscriptstyle \mathrm{I}}})^{\bullet} \mathbf{b} = \mathbf{p}_{\circ} (\sigma^{{\scriptscriptstyle \mathrm{CO}}})^{\bullet} \mathbf{b}$$

i.e.,  $o \in E$ .

The following short calculation, where we use Identity (32) and assume that  $m \in E$ ,

$$\mathbf{p}_{\sigma\sigma m} = \mathbf{b}\sigma^{\bullet}\mathbf{p}_{\sigma m} = \mathbf{b}\sigma^{\bullet}\left(\mathbf{p}_{m}\left(\sigma^{\sigma m}\right)^{\bullet}\mathbf{b}\right) = \left(\mathbf{b}\sigma^{\bullet}\mathbf{p}_{m}\right)\left(\sigma^{\bullet}\circ\left(\sigma^{\sigma m}\right)^{\bullet}\mathbf{b}\right) = \mathbf{p}_{\sigma m}\left(\sigma^{\sigma\sigma m}\right)^{\bullet}\mathbf{b} \qquad \left(m \in N\right),$$

demonstrates that  $\sigma m \in E$ . Invocation of Corollary 2.2 proves that E = N.

# **2.6.3** The (right) product sequence $\left(\prod_{i=0}^{n} b_i\right) = (b_0 \cdots b_n)$

Sequence  $Q_n$ , traditionally denoted

$$\prod_{i=0}^{n} b_{i} \quad \text{or} \quad b_{\circ} \cdots b_{n},$$

is defined by the recursive data

$$Q_o = b_o$$
 and  $Q_{\sigma n} = Q_n b_{\sigma n}$   $(n \in N)$ . (35)

By substituting n = 0 into Identity (32) and noticing that

$$\sigma^{\sigma m}(o) = \sigma m$$

we obtain the following corollary.

Corollary 2.13 One has

$$\prod_{i=0}^{m} b_i = p_{mo} \qquad (m \in N).$$

In particular, the product sequence exists for any sequence  $(b_n)$  of elements in a semigroup.

# **2.6.4** The (left) product sequence $\left(\prod_{i=n}^{o} b_i\right) = (b_n \cdots b_o)$

The left product sequence  $P_n$  is defined by the recursive data

$$P_{o} = b_{o}$$
 and  $P_{\sigma_{n}} = b_{\sigma_{n}} P_{n}$   $(n \in N)$ . (36)

The left product sequence coincides with the (right) product sequence in the *opposite* semigroup  $(B,,)^{op}$ .

# **2.6.5** The sum sequence $\left(\sum_{i=0}^{n} b_i\right) = (b_0 + \dots + b_n)$

In a commutative semigroup the product sequence becomes, in additive notation, the *sum sequence*, denoted

$$\sum_{i=0}^{n} b_{i} \qquad \text{or} \qquad b_{o} + \dots + b_{n} \qquad (n \in N).$$
(37)

Proposition 2.14 For any recursive data (14)-(15), there exists a unique sequence defined by those data.

Proof. Let

$$\bar{\tau}_n = \begin{cases} \tau_m & \text{if } \sigma m = n \\ \text{id}_X & \text{if } n = 0 \end{cases}$$

and

$$T_n = \bar{\tau}_n \circ \dots \circ \bar{\tau}_{\Omega} \qquad (n \in N)$$

be the left product sequence in the semigroup of unary operations (Op $_{_{\rm I}}X,\circ$ ). The sequence

$$x_n := T_n(x_0) \qquad (n \in N) \tag{38}$$

satisfies recursive data (14)-(15). Uniqueness was proved earlier, cf. Lemma 2.9.

# 2.7 Homomorphisms $(N, \sigma) \longrightarrow (X, \tau)$

#### 2.7.1

Any homomorphism

$$\mathbf{x}: (N, \sigma) \longrightarrow (X, \tau) \tag{39}$$

of twisted sets is simultaneously a homomorphism of nullary unary structures

$$(N, o, \sigma) \longrightarrow (X, x, \tau)$$
 (40)

where  $x := x_0$ . Thus, the set of homomorphisms (39) is the union

$$\operatorname{Hom}_{\operatorname{Set}^{(1)}}((N,\sigma),(X,\tau)) = \bigcup_{x \in X} \operatorname{Hom}_{\operatorname{Set}^{(1)}}((N,o,\sigma),(X,x,\tau)) \tag{41}$$

of the disjoint family, indexed by elements of X, of the sets of homomorphisms (40).

#### 2.7.2

Each set

$$\operatorname{Hom}_{\operatorname{Set}^{(1)}}((N, o, \sigma), (X, x, \tau))$$

has exactly one element, namely the unique homomorphism (40). We established the following important fact.

**Lemma 2.15** For every twisted set  $(X, \tau)$ , there exists a canonical bijective correspondence

$$\operatorname{Hom}_{\operatorname{Set}^{(1)}}\!\!\big((N,\sigma),(X,\tau)\big)\longleftrightarrow X, \qquad \mathbf{x}\;\longmapsto\;x_{\mathrm{o}}\,. \tag{42}$$

The reverse correspondence assigns to an element  $x \in X$  the unique homomorphism (40).

Corollary 2.16 There exists a canonical bijective correspondence

$$\operatorname{End}_{\operatorname{Set}^{(1)}}(N,\sigma) \longleftrightarrow N, \qquad \sigma^m \longleftrightarrow \sigma^m(o) = m. \tag{43}$$

*Proof.* Consider the set

$$E = \{ m \in N \mid \sigma^m(o) = m \}.$$

Since  $\sigma^{\circ} = id_N$ , one has  $o \in E$ . If  $m \in N$ , then

$$\sigma^{\sigma m}(o) = \sigma(\sigma^m(o)) = \sigma m$$
,

i.e., E is closed under o and  $\sigma$ . By Corollary 2.2, E equals N.

By combining this with Lemma 2.15, we deduce that powers of  $\sigma$  are the only unary operations on N that commute with  $\sigma$ ,

$$\sigma^m = \sigma^n$$
 if and only if  $m = n$   $(m, n \in N)$ . (44)

and

$$\operatorname{End}_{\operatorname{Set}^{(1)}}(N,\sigma) = \bigcup_{m \in \mathbb{N}} \operatorname{Hom}_{\operatorname{Set}^{(1)}}((N,o,\sigma),(N,m,\sigma)) = \bigcup_{m \in \mathbb{N}} \{\sigma^m\}. \tag{45}$$

#### 2.7.3 The canonical commutative monoid structure on N

Since composition of endomorphisms makes  $\operatorname{End}_{\operatorname{Set}^{(1)}}(N,\sigma)$  a monoid, canonical bijection (43) equips N with a canonical monoid structure:

$$id_N = \sigma^{\circ} \longleftrightarrow o$$
 and  $\sigma^m \circ \sigma^n \longleftrightarrow m + n$   $(m, n \in N)$ . (46)

Exercise 15 Prove that

$$\sigma n = 1 + n. \tag{47}$$

Solution. Under Correspondence (46), one has

$$\sigma^{\sigma n} \longleftrightarrow \sigma n$$
 and  $\sigma^{1} \circ \sigma^{n} \longleftrightarrow 1 + n$   $(n \in N)$ .

By the definition of the power sequence  $(\sigma^n)$ , one has

$$\sigma^{\sigma n} = \sigma \circ \sigma^n = \sigma^1 \circ \sigma^n \qquad (n \in N)$$

in view of  $\sigma^1 = \sigma$ , cf. (23). Since  $\sigma^{\sigma n} = \sigma^1 \circ \sigma^n$ , one has  $\sigma n = 1 + n$ .

#### 2.7.4

Since powers  $\sigma^n$  are the only endomorphisms of  $(N, \sigma)$ , all elements of  $\operatorname{End}_{\operatorname{Set}^{(1)}}(N, \sigma)$  commute with each other, cf. Lemma 2.10. In particular, (N, 0, +) is a commutative monoid.

#### 2.7.5 Additive notation for commutative semigroups and monoids

The binary operation in a commutative semigroup is frequently referred to as *addition* and + is used as the generic symbol for addition. The identity element of addition is frequently referred to as the zero element and is denoted 0.

**Lemma 2.17** Addition in (N, 0, +) has the property

if 
$$l + m = l + n$$
, then  $m = n$   $(l, m, n \in N)$ . (48)

The above lemma says that (N, o, +) is a cancellative monoid.

#### 2.7.6 Cancellative binary structures

A binary algebraic structure  $(B,\cdot)$  is said to be *left-cancellative* if it has the following property:

if 
$$ab = ac$$
, then  $b = c$   $(a, b, c \in B)$ , (49)

and it is said to be *right-cancellative* if it has the following property:

if 
$$ac = bc$$
, then  $a = b$   $(a, b, c \in B)$ . (50)

We refer to (49) and (50) as the *Left-Cancellation Property* and, respectively, the *Right-Cancellation Property*. When the binary operation is commutative, the two cancellation properties coincide.

Proof of Lemma 2.17. One has

$$l+m=\sigma^{l+m}(o)=(\sigma^l\circ\sigma^m)(o)=\sigma^l(m)$$

and, similarly,

$$l+n=\sigma^{l+n}(o)=(\sigma^l\circ\sigma^n)(o)=\sigma^l(n)$$
.

Thus, equality l + m = l + n is equivalent to the equality

$$\sigma^l(m)=\sigma^l(n).$$

According to Theorem 2.8, successor operation  $\sigma$  is injective. It follows that  $\sigma^l$  is injective, cf. Exercise 11, hence m=n.

### 2.8 The canonical well-ordering of N

#### 2.8.1 The canonical order relation $\leq$ on N

Consider the binary relation on N,

$$\leq : m, n \longmapsto \text{``} \exists_{l \in N} l + m = n \text{''}. \tag{51}$$

Since addition in (N, 0, +) is cancellative, cf. Lemma (2.17), an element  $l \in N$  such that l+m=n is unique when it exists.

Exercise 16 Show that relation  $\leq$  is reflexive.

Exercise 17 Show that relation  $\leq$  is transitive.

Exercise 18 Show that, for any  $l, m \in N$ ,

if 
$$l + m = 0$$
, then  $l = m = 0$ . (52)

Exercise 19 Show that relation  $\leq$  is weakly antisymmetric.

#### 2.8.2 Remarks concerning valid solutions of the above exercises

Use exclusively the facts established in these notes, and only those facts that were established prior to the statement of the above exercises. Your proofs should provide explicit, clear references to the facts you are relying upon at various places of your proofs. References must be correct and they must be mentioned where they are relevant.

#### 2.8.3 The associated sharp order relation < on N

We shall use symbol < to denote the relation

$$\langle m, n \mapsto m \leq n \wedge m \neq n \rangle.$$
 (53)

Since  $l \neq 0$  implies that  $l = \sigma k$ , for some  $k \in N$ , cf. Corollary 2.3, relation (53) is equipotent with the relation

$$m, n \longmapsto " \exists_{k \in N} \ \sigma k + m = n " \tag{54}$$

which, in turn, is equipotent with the relation

$$m, n \mapsto " \sigma m \le n "$$
 (55)

in view of the identity

$$\sigma k + m = (1 + k) + m = (k + 1) + m = k + (1 + m) = k + \sigma m$$
.

Exercise 20 Show that  $m \le n$  if and only if  $m < \sigma n$ .

Exercise 21 Show that

if 
$$m < n$$
, then  $k + m < k + n$ . (56)

#### 2.8.4 Ordered semigroups

. Commutative semigroups equipped with an order relation that satisfy Property (56) are called ordered semigroups.

**Proposition 2.18**  $(N, \leq)$  is a well-ordered set.

Proof. Consider the subset

$$E = \{ n \in N \mid \forall_{m \in N} \ m \le n \lor n \le m \} .$$

Since n + o = n, element o is the smallest element of  $(N, \leq)$  and  $o \in E$ .

If  $m \not\leq \sigma n$ , then  $m \not\leq n$ , in view of the inequality  $n < \sigma n$ . If, additionally,  $n \in E$ , then n < m or, equivalently, cf. Section 2.8.3,

$$\sigma n \leq m$$
,

i.e.,  $\sigma n \in E$ . Invocation of Corollary 2.2 proves that E = N. That means that  $\leq$  is a *linear order* relation.

Consider the subset

$$F = \left\{ n \in N \mid \forall_{A \subseteq N} \left( \exists_{k \in A} \ k \le n \right) \Longrightarrow \left( \exists_{m \in A} \ m = \min A \right) \right\}.$$

Since o is the smallest element of  $(N, \leq)$ , it is the smallest element of any subset  $A \ni o$ . In particular,  $o \in F$ .

The condition

$$\exists_{k \in A} \ k \leq \sigma n$$

is equivalent to the alternative

$$\left(\exists_{k \in A} \ k \le n\right) \lor \left(\sigma n \in A \land \forall_{k \le n} \ k \notin A\right) \tag{57}$$

If  $n \in F$  and the first part of alternative statemnt (57) holds, then A has the smallest element.

If the second part of alternative (57) holds, then the already proven linear-ordering of  $(N, \leq)$  implies that

$$\forall_{m \in A} \ n < m$$

and, accordingly,  $\sigma n$  is the smallest element of A. This demonstrates that  $\sigma n \in F$ . Yet another invocation of Corollary 2.2 proves that F = N.

# Homomorphisms $(N, o, +) \longrightarrow (B, e, \cdot)$

#### 2.9.1

Homomorphisms

$$(N, o, +) \longrightarrow (B, e, \cdot) \tag{58}$$

are precisely the sequences  $\mathbf{x}: N \longrightarrow B$  such that

$$x_{o} = e$$
 and  $x_{m+n} = x_{m}x_{n}$   $(m, n \in N)$ . (59)

**Lemma 2.19** For any  $b \in B$ , the sequence of powers  $(b^n)$  is a homomorphism of monoids (58).

*Proof.* Let  $b \in B$ . Consider the set

$$E = \{ m \in N \mid \forall_{n \in N} b^{m+n} = b^m b^n \}$$

In view of equalities

$$o + n = n$$
 and  $b^{\circ} = e$ 

one has

$$b^{\circ + n} = b^n = eb^n = b^{\circ}b^n,$$

i.e,  $o \in E$ . If  $m \in E$ , then

$$b^{\sigma m+n} = b^{(1+m)+n} = b^{1+(m+n)} = b^{\sigma(m+n)} = bb^{m+n} = bb^m b^n = b^{\sigma m} b^n,$$
 (60)

i.e., E is closed under  $\sigma$ . Hence, by Corollary 2.2, E = N.

Note that calculation (60) used associativity of addition in N, Identity (47), and equality  $\sigma^{\text{I}} = \sigma$ .

#### 2.9.2

Consider the evaluation-at-1 function,

$$\operatorname{ev}_{\scriptscriptstyle{\mathbf{I}}}: \operatorname{Hom}_{\operatorname{Mon}}((N, o, +), (B, e, \cdot)) \longrightarrow B, \quad \mathbf{x} \longmapsto x_{\scriptscriptstyle{\mathbf{I}}}.$$
 (61)

**Lemma 2.20** Canonical correspondence (61) is bijective and the reverse correspondence assigns to an element  $b \in B$  the sequence of powers  $(b^n)$ .

*Proof.* It suffices to prove injectivity of the evaluation at 1 function. Let  $\mathbf{x}$  and  $\mathbf{x}'$  be two homomorphisms (58) such that  $x_1 = x_1'$ . Consider the set

$$E = \{n \in N \mid x_n = x_n'\}.$$

Since  $x_0 = 0$ , for any homomorphism (58), one has  $0 \in E$ . If  $n \in E$ , then

$$x_{\sigma n} = x_{1+n} = x_1 x_n = x_1' x_n' = x_{1+n}' = x_{\sigma n}',$$

i.e., E is closed under  $\sigma$ . Hence, by Corollary 2.2, E = N.

#### 2.9.3 (N, 0, 1, +) is an initial object in the category of monoids with a distinguished element

Note that Lemmata 2.19-2.20 imply that, for any element b in any monoid  $(B, e, \cdot)$ , there exists a unique homomorphism

$$(N, 0, 1, +) \longrightarrow (B, e, b, \cdot),$$
 (62)

i.e., (N, 0, 1, +) is an initial object in the category of monoids with a distinguished element.

#### 2.9.4

Homomorphisms (58) are sequences of elements of B. Sequences can be multiplied using multiplication in B,

$$(x_n) \cdot (y_n) := (x_n y_n). \tag{63}$$

The set of homomorphisms is closed under multiplication when multiplication is commutative.

#### 2.9.5

Let X be a set and  $(B,\cdot)$  be a semigroup. The set of B-valued functions

is equipped with the induced binary operation

$$(f \cdot g)(x) \coloneqq f(x) \cdot g(x). \tag{64}$$

**Exercise 22** Let  $(X, \cdot)$  be a binary structure and  $(B, \cdot)$  be a semigroup. Show that if f and g are homomorphisms

$$(X,\cdot) \longrightarrow (B,\cdot)$$
 (65)

such that,

$$f(x) \cdot g(y) = g(y) \cdot f(x) \qquad (x, y \in X), \tag{66}$$

then  $f \cdot g$  is a homomomorphism (65).

**Lemma 2.21** If elements a and b of a monoid  $(B, e, \cdot)$  commute with each other, then

$$a^n b^n = (ab)^n \qquad (n \in N). \tag{67}$$

*Proof.* If a and b commute, then,  $a^m$  and  $b^n$  commute for all  $m, n \in N$ , cf. Part (b) of Corollary 2.11. Therefore, the product sequence

$$(a^nb^n)$$

is, by Exercise 22, a homomorphism (58). Its value at n=1 equals

$$a^{\mathbf{I}}b^{\mathbf{I}}=ab$$
.

Since there is only one homomorphism (58) that takes this value, namely the sequence of powers

$$(ab)^n$$
,

Identity (67) folows.

#### 2.9.6

Note how brilliant is this purely algebraic proof of a nontrivial identity.

**Lemma 2.22** For any element  $b \in B$  of a monoid, one has the following identity

$$(b^m)^n = (b^m)^n \qquad (m, n \in N).$$
 (68)

*Proof.* Consider the set

$$E = \{ n \in N \mid \forall_{m \in N} (b^m)^n = (b^m)^n \}.$$

One has

$$(b^m)^\circ = e = e^m = (b^\circ)^m \qquad (m \in N),$$

hence  $o \in E$ . If  $n \in N$ , then

$$(b^m)^{\sigma n} = (b^m)^{1+n} = b^m (b^m)^n = (b^1)^m (b^n)^m$$
.

Since  $b^{1}$  commutes with  $b^{n}$ , we have, in view of Lemma 2.21,

$$(b^{\scriptscriptstyle 1})^m (b^n)^m = (b^{\scriptscriptstyle 1+n})^m = (b^{\sigma n})^m,$$

i.e.,  $\sigma n \in E$ . Corollary 2.2 implies that E = N.

**2.9.7** 
$$\operatorname{Hom}_{\operatorname{Mon}}((N, o, +), (A, o, +))$$

When the target is a commutative monoid and we use additive notation, the n-th power of an element  $a \in A$  is then denoted na and referred to as n times a. In additive notation and terminology, Lemma 2.20 reads as follows.

**Lemma 2.23** For a commutative monoid (A, 0, +), the reverse correspondence to (61) assigns to an element  $a \in A$  the sequence of n-tuples (na).

## 2.10 Semirings: terminology

#### 2.10.1 Semirings

An algebraic structure  $(S, +, \cdot)$  is said to be an (associative) *semiring* if it satisfies the following three conditions:

- (a) (S, +) is a commutative semigroup;
- (b)  $(S, \cdot)$  is a semigroup;
- (c) operation · , referred to as multiplication, right- and left-distibutes over operation + , referred to as addition.

#### 2.10.2 Unital semirings

An algebraic structure  $(S, 1, +, \cdot)$  is said to be a *unital semiring* if it satisfies the following two conditions:

- $(a_1)$   $(S, +, \cdot)$  is a semiring;
- $(b_1)$   $(S, 1, \cdot)$  is a monoid.

#### 2.10.3 Semirings-with-zero

An algebraic structure  $(S, o, +, \cdot)$  is said to be a *semiring-with-zero* if it satisfies the following two conditions:

- $(a_o)$   $(S, +, \cdot)$  is a semiring;
- $(b_o)$  (S, o, +) is a monoid.

Usually, one also adds the requirement that

 $(c_0)$   $(S, 0, \cdot)$  is a semigroup with sink, i.e.,

$$o \cdot s = o = s \cdot o \qquad (s \in S). \tag{69}$$

#### 2.10.4 Unital semirings-with-zero

An algebraic structure  $(S, 0, 1, +, \cdot)$  is said to be a *unital semiring-with-zero* if it satisfies the following three conditions:

- $(a_{oi})$   $(S, +, \cdot)$  is a semiring;
- $(b_{oi})$  (S, o, +) is a monoid;
- $(c_{oi})$   $(S, i, \cdot)$  is a monoid.

## 2.11 The unital semiring of endomorphisms of a commutative semigroup (A,+)

## 2.11.1 Commutative semigroup (Funct(X, A), +)

Let (A, +) be a commutative semigroup. The set

of A-valued functions on a set X, equipped with the induced binary operation,

$$(f+g)(x) := f(x) + g(x)$$
  $(f,g \in Funct(X,A); x \in X),$  (70)

becomes a commutative semigroup.

**2.11.2** 
$$(Op_{A}, id_{A}, +, \circ)$$

Consider a special case X = A. In this case Funct(X, A) is the set of unary operations on A, equipped with the canonical monoid structure  $(\operatorname{Op}_{_{1}}A, \operatorname{id}_{_{A}}, \circ)$ . The subset of  $\operatorname{Op}_{_{1}}A$  consisting of endomorphisms of semigroup (A, +) contains the identity operation  $\operatorname{id}_{A}$  and is closed under composition, i.e., is a *submonoid* of  $(\operatorname{Op}_{_{1}}A, \operatorname{id}_{_{A}}, \circ)$ .

#### 2.11.3 Right-distributivity of over +

Addition of unary operations on A equips  $\operatorname{Op}_{_{\mathbf{I}}}A$  with another binary operation that is both associative and commutative. Composition is right-distributive with respect to addition.

Exercise 23 Show that, for any  $f, g, h \in Op_A$ , one has

$$(f+g) \circ h = f \circ h + g \circ h. \tag{71}$$

#### 2.11.4 Limited left-distributivity of over +

Composition, in general, is *left-distributive* with respect to addition only when the left factor h is an endomorphism of semigroup (A, +).

Exercise 24 Show that, for any  $f, g \in \operatorname{Op}_A A$  and  $h \in \operatorname{End}_{\operatorname{Sor}}(A, +)$ , one has

$$h \circ (f+g) = h \circ f + h \circ g. \tag{72}$$

# 2.11.5 The unital semiring $\left(\operatorname{End}_{\operatorname{Sgr}}(A,+),\operatorname{id}_A,+,\circ\right)$

The subset consisting of endomorphisms (A, +) is closed under addition.

**Exercise 25** Show that, if f and g are endomorphisms of (A, +), then f + g is an endomorphism.

By combining previous three exercises, we deduce that the algebraic structure  $\left(\operatorname{End}_{\operatorname{Sgr}}(A,+),\operatorname{id}_A,+,\circ\right)$  is a *unital semiring*.

## 2.11.6 The unital semiring-with-zero (End<sub>Mon</sub> $(A, o, +), 0, id_A, +, \circ$ )

If (A, o, +) is a commutative monoid, then the subset in  $\operatorname{Op}_1 A$  consisting of endomorphisms of (A, o, +) is unital semiring with the constant zero function

$$\mathbf{0}: A \longrightarrow A, \qquad x \longmapsto 0, \tag{73}$$

being its zero element.

Exercise 26 Show that, for any operation  $f \in Op_A$ , one has

$$\mathbf{0} \circ f = \mathbf{0}$$
,

and, for any endomorphism of nullary structures  $g:(A,o)\to (A,o)$ , one has also

$$g \circ \mathbf{0} = \mathbf{0}$$
.

It follows that the constant zero function 0 is a sink for the operation of composition of endomorphisms of a commutative monoid (A, o, +).

#### 2.11.7 The canonical commutative unital semiring-with-zero structure on N

Since  $\operatorname{End}_{\operatorname{Mon}}(N, o, +)$  is naturally equipped with a structure of a unital semiring-with-zero, canonical bijection (61) equips N with a canonical structure of a commutative unital semiring-with-zero.

By recalling that the monoid stucture (N, 0, +) is a translation, via bijective correspondence (43), of the monoid structure on  $\operatorname{End}_{\operatorname{Set}^{(o1)}}(N, \sigma)$ , we shall now describe the operations of  $(N, 0, 1, +, \cdot)$  in terms the corresponding operations on the set of endomorphisms of

$$\operatorname{End}_{\operatorname{Set}^{\langle \operatorname{oi} \rangle}}(N,\sigma) = \{\sigma^n \mid n \in N\}.$$

Addition in  $(N, 0, 1, +, \cdot)$  corresponds to the composition operation

$$m + n \longleftrightarrow \sigma^m \circ \sigma^n$$
 (74)

and multiplication in  $(N, 0, 1, +, \cdot)$  corresponds to the exponentiation operation

$$mn \longleftrightarrow \sigma^m * \sigma^n := (\sigma^m)^n$$
 (75)

Commutativity of multiplication in  $(N, 0, 1, +, \cdot)$  is an immediate corollary of Lemma 2.22

**Corollary 2.24** Multiplication in  $(N, 0, 1, +, \cdot)$  is commutative.

#### 2.11.8

The canonical semiring structure on the underlying set of an initial object  $(N, o, \sigma)$  of the category of nullary-unary structures is what we know, on informal level, as "Arithmetic of Natural Numbers."

**Lemma 2.25** Semiring  $(N, 0, 1, +, \cdot)$  has the following property

if 
$$0 < m, n$$
, then  $0 < mn$ . (76)

*Proof.* If 0 < m, n, then  $m = \sigma k = 1 + k$  and  $n = \sigma l = 1 + l$ , cf. Corollary 2.3 and Exercise 15. Distributivity of multiplication over addition yields

$$0 < 1 \le 1 + kl + km = (1 + k)(1 + l) = mn$$
.

#### 2.11.9 Ordered semirings

Semirings equipped with an order relation such that the additive semigroup is an ordered semigroup, i.e., it satisfies Property (56), and the multiplicative semigroup satisfies Property (76), are called ordered semirings.
